

What the September numbers show

Six things worth knowing from 20,000 orders placed in September 2024.

1 day

took down two
whole markets

2 stores

losing driver and
billing data

3,240 a yr

orders confirmed,
then dropped

15x

more orders at
night than morning

Two cities lost every order on September 4

One system failure took down whole markets, and nobody caught it until the end of the month.

What happened

Las Vegas and Memphis only had orders on September 4, and every one of them failed. This was one bad day, not random noise.

122

orders failed
that day

90

customers got
nothing

\$4.4K

order value lost
in one day

4

regions hit at
the same time

RECOMMENDATION

Have ops and engineering root-cause the September 4 outage, and make sure a region-wide failure is caught the same day, not at month end.

Failed orders as a share of each region's month

EXECUTION

Add a market heartbeat: an automatic alert that pages on-call the moment a region's completion rate drops below its own baseline.

Two restaurants are losing order data

Each has its own repeating problem, separate from the September 4 failure.

Store 25675466, losing driver records

- 40.5% of its orders (15 of 37) were delivered but lost the driver and payment records
- It happened on two different dates three weeks apart, so this keeps recurring
- 13 customers were affected

Store 135488, losing the payment

- 10.5% of its orders (113 of 1,081) were delivered but recorded as \$0
- It averages \$37.56 on its other orders, so real money is going unrecorded
- About \$4,244 in revenue was never recorded, across 73 customers

RECOMMENDATION

Fix the two stores' data leak, and make partner data problems surface on their own instead of turning up weeks later by accident.

Broken records by store

EXECUTION

Check both point-of-sale connections, then add a payment-health flag showing orders where a store's payout is at risk, so they fix it to get paid.

DASHERS

CUSTOMERS

A small daily leak that adds up to 3,240 orders a year

Every day a handful of orders get confirmed by the restaurant and then never go out.

Steady all month, not a one time spike

**270 a mo**

confirmed, then
never sent

244

customers hit
this month

Scheduled orders fail almost 4 times as often

**3,240 a yr**

if it keeps
going

\$3,625

refunds this
month

RECOMMENDATION

Watch non-delivery as a weekly number, and cut the scheduled-order failure rate, which runs about 3.8 times the ASAP rate.

EXECUTION

Let Dashers reserve scheduled orders ahead for priority, so each has a committed Dasher, and notify the restaurant before pickup.

This is a nighttime business

Orders pile up late at night and nearly disappear in the morning. Plan around it.

Customer count

Drivers per customer (colour) and distinct count of Customer Id (size) broken down by Order weekday vs. Order hour and Order hour label. The data is filtered on Delivery Region and Is Asap. The Delivery Region filter keeps 56 members. The Is Asap filter keeps True.

Your Customer count heatmap, by hour and day.

What the chart shows

- Size of each block = customers that hour
- Color = drivers per customer

The size is the demand curve: fat late at night, nearly gone from 7 to 9am. The 9pm to 2am block has 8,943 orders vs 577 from 6 to 11am, fifteen times more at night.

The color, drivers per customer, sits near 0.85 but climbs toward 1.0 in the thin morning hours (0.91 vs 0.84). Drivers wait in the morning, not in short supply.

RECOMMENDATION

Point driver supply, incentives, and marketing at the night, where the business is.

EXECUTION

A peak earnings signal shows Dashers where pay peaks, 9pm to 2am, so top-up pulls supply there.

Morning orders wait longest on the kitchen

The slow part of a morning delivery is the food getting ready, not the drive.

Prep time and revenue

Average of Revenue (colour) and median of prep time (size) broken down by Order weekday vs. Order hour and Order hour label. The data is filtered on Delivery Region and Is Asap. The Delivery Region filter keeps 56 members. The Is Asap filter keeps True.

Your Prep time and revenue heatmap, by hour and day.

What the chart shows

- Size = median time to hand off the food
- Color = revenue per order

Revenue = Order Total - Discount - Refunded

Prep time is highest in the morning, about 15 minutes to hand off the food against 9 midday. The wait is the kitchen, not the drive.

Revenue is lowest at the same time, near \$27 against \$42 late at night. Mornings are breakfast, so the slowest handoffs land on the least valuable orders.

RECOMMENDATION

Keep driver spend light: morning is low-value and already has enough drivers.

EXECUTION

Set an honest, longer morning ETA. If demand rises, dynamic top-up pay covers the supply automatically.

Refunds track kitchen prep time

Overall refunds are low at 1.37%, but they climb where the food takes longest to hand off.

Driver count & refund

Refund rate (colour) and distinct count of Driver Id (size) broken down by Order weekday vs. Order hour and Order hour label. The data is filtered on Delivery Region and Is Asap. The Delivery Region filter keeps 56 members. The Is Asap filter keeps True.

Your Driver count & refund heatmap, by hour and day.

What the chart shows

- Color = refund rate
- Size = number of drivers

Refunds are low overall, 1.37%, but they move with prep time across the day (correlation about 0.4). The hours with the slowest kitchens carry more refunds.

It is clearest in the morning: the 15 minute handoffs from 6 to 10am run a 1.75% refund rate against 1.32% the rest of the day. Weekend late nights also run high.

RECOMMENDATION

Get restaurants to cut morning prep time; faster kitchens mean shorter waits and fewer refunds.

EXECUTION

A customer-facing fast-prep badge plus prep time in ranking makes faster kitchens win orders. No cash.
